

Economies of agglomeration on fast growth companies

Marc Pérez Bernús

September 10, 2020

Data acquisition and cleaning

The data that will be used will be the EMEA Fast Growth 500 annual report of Deloitte and the location of the business clusters listed on wikipedia by city. A part of the Foursquare API to locate the services around the companies and the google API to get the coordinates to be mapped by the same companies are going to be crucial for the goal setted on the introduction.

The PDF will be converted to csv and cleaned of NaN and other unuseful data such as the number of pages, titles and others. Having the DataFrame created will be interesting to select the countries and the industries sectors with more companies in order to get relevant data. As the report just shows the rate growth, the name of the company, country and industry sector, using the geocoder API of google will be a must due to the fact that can recognise the name of the companies without the address.

Create a last DataFrame merging the original with the new one with the latitude and longitude of the companies will be used to make the call to the API and later on visualize through folium the location and clustering using K-Means.
